

ANSWERS

1. The actual code

```
int startValue = 5;
```

```
int ledPin =13;
```

```
void flashLed(int times){
```

```
    int blinkCount =0;
```

```
    while(blinkCount<times){
```

```
        digitalWrite(ledPin,HIGH);
```

```
        delay(300);
```

```
        digitalWrite(ledPin,LOW);
```

```
        delay(300);
```

```
        blinkCount++;
```

```
    }
```

```
}
```

```
void setup() {
```

```
    // put your setup code here, to run once:
```

```
    pinMode(ledPin,OUTPUT);
```

```
    Serial.begin(9600);
```

```
    Serial.println("====Smart countdown starting====");
```

```
    int count = startValue;
```

```

while(count >=1){
  Serial.print("count:");
  Serial.println(count);

  flashLed(count);
  delay(1000);
  count = count -1;
}

Serial.println("=====Countdown complete====");
}

void loop() {
  // put your main code here, to run repeatedly:

```

2. One mistake I forgot to do was to reduce the value of count inside the while loop. This caused the program run forever because the loop condition never becomes false. I fixed it by adding `count =count-1` at the end of the loop.

3.I would change the `count = count-1;` to `count = count-2;`

4. I would add it after the `(Serial.println("=====Countdown complete===="));`

The code I will add is;

```

digitalWrite(ledPin,HIGH);
delay(50000);
digitalWrite(ledPin,LOW);

```
